

ASSIGNMENT-2

Name: Pusalapati Chandu

Reg no: 192372119

1. Counting Elements

Given an integer array `arr`, count how many elements `x` there are, such that `x + 1` is also in

`arr`. If there are duplicates in `arr`, count them separately.

Example

Input: `arr = [1,2,3]`

Output: 2

Explanation: 1 and 2 are counted cause 2 and 3 are in `arr`.

Example 2:

Input: `arr = [1,1,3,3,5,5,7,7]`

Output: 0

Explanation: No numbers are counted, cause there is no 2, 4, 6, or 8 in `arr`.

Constraints:

● $1 \leq \text{arr.length} \leq 1000$

● $0 \leq \text{arr}[i] \leq 1000$

```
def count_elements(arr):  
    count = 0  
    for num in arr:  
        if num + 1 in arr:  
            count += 1  
    return count  
print(count_elements([1,2,3]))
```

```
Python 3.12.2

2. Perform String Shifts

You are given a string s containing lowercase English letters, and a matrix shift, where

$\text{shift}[i] = [\text{direction}_i, \text{amount}_i]$:

- direction_i can be 0 (for left shift) or 1 (for right shift).
- amount_i is the amount by which string s is to be shifted.
- A left shift by 1 means remove the first character of s and append it to the end.
- Similarly, a right shift by 1 means remove the last character of s and add it to the beginning.

Return the final string after all operations.

Example 1:

Input: $s = \text{"abc"}$, $\text{shift} = [[0,1],[1,2]]$

Output: "cab"

Explanation:

[0,1] means shift to left by 1. "abc" -> "bca"

[1,2] means shift to right by 2. "bca" -> "cab"

Example 2:

Input: s = "abcdefg", shift = [[1,1],[1,1],[0,2],[1,3]]

Output: "efgabcd"

Explanation:

[1,1] means shift to right by 1. "abcdefg" -> "gabcdef"

[1,1] means shift to right by 1. "gabcdef" -> "fgabcde"

[0,2] means shift to left by 2. "fgabcde" -> "abcdefg"

[1,3] means shift to right by 3. "abcdefg" -> "efgabcd"

Constraints:

- $1 \leq s.length \leq 100$
- s only contains lower case English letters.
- $1 \leq shift.length \leq 100$
- $shift[i].length == 2$
- directioni is either 0 or 1.
- $0 \leq amount_i \leq 100$

```
def stringShift(s, shift):
    n = len(s)
    total_shift = 0
    for direction, amount in shift:
        if direction == 0:
            total_shift += amount
        else:
            total_shift -= amount
    total_shift %= n
    return s[total_shift:] + s[:total_shift]
print(stringShift("abc", [[0,1],[1,2]]))
```

3. Leftmost Column with at Least a One

A row-sorted binary matrix means that all elements are 0 or 1 and each row of the matrix

is sorted in non-decreasing order.

Given a row-sorted binary matrix `binaryMatrix`, return the index (0-indexed) of the

leftmost column with a 1 in it. If such an index does not exist, return -1.

You can't access the Binary Matrix directly. You may only access the matrix using a

BinaryMatrix interface:

- `BinaryMatrix.get(row, col)` returns the element of the matrix at index (row, col)

(0-indexed).

- `BinaryMatrix.dimensions()` returns the dimensions of the matrix as a list of 2

elements [rows, cols], which means the matrix is rows x cols.

Submissions making more than 1000 calls to BinaryMatrix.get will be judged Wrong

Answer. Also, any solutions that attempt to circumvent the judge will result in

disqualification.

For custom testing purposes, the input will be the entire binary matrix mat. You will not

have access to the binary matrix directly.

Example 1:

Input: mat = [[0,0],[1,1]]

Output: 0

Example 2:

Input: mat = [[0,0],[0,1]]

Output: 1

Example 3:

Input: mat = [[0,0],[0,0]]

Output: -1

Constraints:

- rows == mat.length
- cols == mat[i].length

- $1 \leq \text{rows}, \text{cols} \leq 100$
- $\text{mat}[i][j]$ is either 0 or 1.
- $\text{mat}[i]$ is sorted in non-decreasing order.

```
from collections import deque, Counter

class FirstUnique:
    def __init__(self, nums: list[int]):
        self.queue = deque(nums)
        self.counts = Counter(self.queue)
        self.unique_queue = deque()

        # Populate the unique_queue with the first unique elements
        for num in nums:
            if self.counts[num] == 1:
                self.unique_queue.append(num)

    def showFirstUnique(self) -> int:
        # Remove non-unique elements from the front of the unique_queue
        while self.unique_queue and self.counts[self.unique_queue[0]] > 1:
            self.unique_queue.popleft()

        # Return the first element of the unique_queue if it's not empty, otherwise return -1
        return self.unique_queue[0] if self.unique_queue else -1

    def add(self, value: int) -> None:
        self.queue.append(value)
        self.counts[value] += 1

        # If the added value becomes unique, add it to the unique_queue
        if self.counts[value] == 1:
            self.unique_queue.append(value)

# Example usage:
firstUnique = FirstUnique([2,3,5])
print(firstUnique.showFirstUnique())
```

4. First Unique Number

You have a queue of integers, you need to retrieve the first unique integer in the queue.

Implement the FirstUnique class:

- `FirstUnique(int[] nums)` Initializes the object with the numbers in the queue.

- `int showFirstUnique()` returns the value of the first unique integer of the queue,

and returns -1 if there is no such integer.

- `void add(int value)` insert value to the queue.

Example 1:

Input:

```
["FirstUnique","showFirstUnique","add","showFirstUnique","add","showFirstUnique","a
```

```
dd","showFirstUnique"]
```

```
[[[2,3,5]],[],[5],[],[2],[],[3],[]]
```

Output:

```
[null,2,null,2,null,3,null,-1]
```

Explanation:

```
FirstUnique firstUnique = new FirstUnique([2,3,5]);
```

```
firstUnique.showFirstUnique(); // return 2
```

```
firstUnique.add(5); // the queue is now [2,3,5,5]
```

```
firstUnique.showFirstUnique(); // return 2
```

```
firstUnique.add(2); // the queue is now [2,3,5,5,2]
```

```
firstUnique.showFirstUnique(); // return 3
```

```
firstUnique.add(3); // the queue is now [2,3,5,5,2,3]
```

```
firstUnique.showFirstUnique(); // return -1
```

Example 2:

Input:

```
["FirstUnique","showFirstUnique","add","add","add","add","add","showFirstUnique"]
```

```
[[[7,7,7,7,7,7]],[],[7],[3],[3],[7],[17],[]]
```

Output:

```
[null,-1,null,null,null,null,null,17]
```

Explanation:

```
FirstUnique firstUnique = new FirstUnique([7,7,7,7,7,7]);
```

```
firstUnique.showFirstUnique(); // return -1
```

```
firstUnique.add(7); // the queue is now [7,7,7,7,7,7,7]
```

```
firstUnique.add(3); // the queue is now [7,7,7,7,7,7,7,3]
```

```
firstUnique.add(3); // the queue is now [7,7,7,7,7,7,7,3,3]
```

```
firstUnique.add(7); // the queue is now [7,7,7,7,7,7,7,3,3,7]
```

```
firstUnique.add(17); // the queue is now [7,7,7,7,7,7,7,3,3,7,17]
```

```
firstUnique.showFirstUnique(); // return 17
```

Example 3:

Input:

```
["FirstUnique","showFirstUnique","add","showFirstUnique"]
```

```
[[[809]],[],[809],[]]
```

Output:

```
[null,809,null,-1]
```

Explanation:

```
FirstUnique firstUnique = new FirstUnique([809]);
```

```
firstUnique.showFirstUnique(); // return 809
```

```
firstUnique.add(809); // the queue is now [809,809]
```

```
firstUnique.showFirstUnique(); // return -1
```

Constraints:

- $1 \leq \text{nums.length} \leq 10^5$
- $1 \leq \text{nums}[i] \leq 10^8$
- $1 \leq \text{value} \leq 10^8$
- At most 50000 calls will be made to showFirstUnique and add.

```

5. Check If a String Is a Valid Sequence from Root to Leaves Path in a Binary Tree

Given a binary tree where each path going from the root to any leaf form a valid

sequence, check if a given string is a valid sequence in such binary tree.

We get the given string from the concatenation of an array of integers arr and the

concatenation of all values of the nodes along a path results in a sequence in the given

binary tree.

Example 1:

Input: root = [0,1,0,0,1,0,null,null,1,0,0], arr = [0,1,0,1]

Output: true

Explanation:

The path 0 -> 1 -> 0 -> 1 is a valid sequence (green color in the figure).

Other valid sequences are:

0 -> 1 -> 1 -> 0

0 -> 0 -> 0

Example 2:

Input: root = [0,1,0,0,1,0,null,null,1,0,0], arr = [0,0,1]

Output: false

Explanation: The path 0 -> 0 -> 1 does not exist, therefore it is not even a sequence.

Example 3:

Input: root = [0,1,0,0,1,0,null,null,1,0,0], arr = [0,1,1]

Output: false

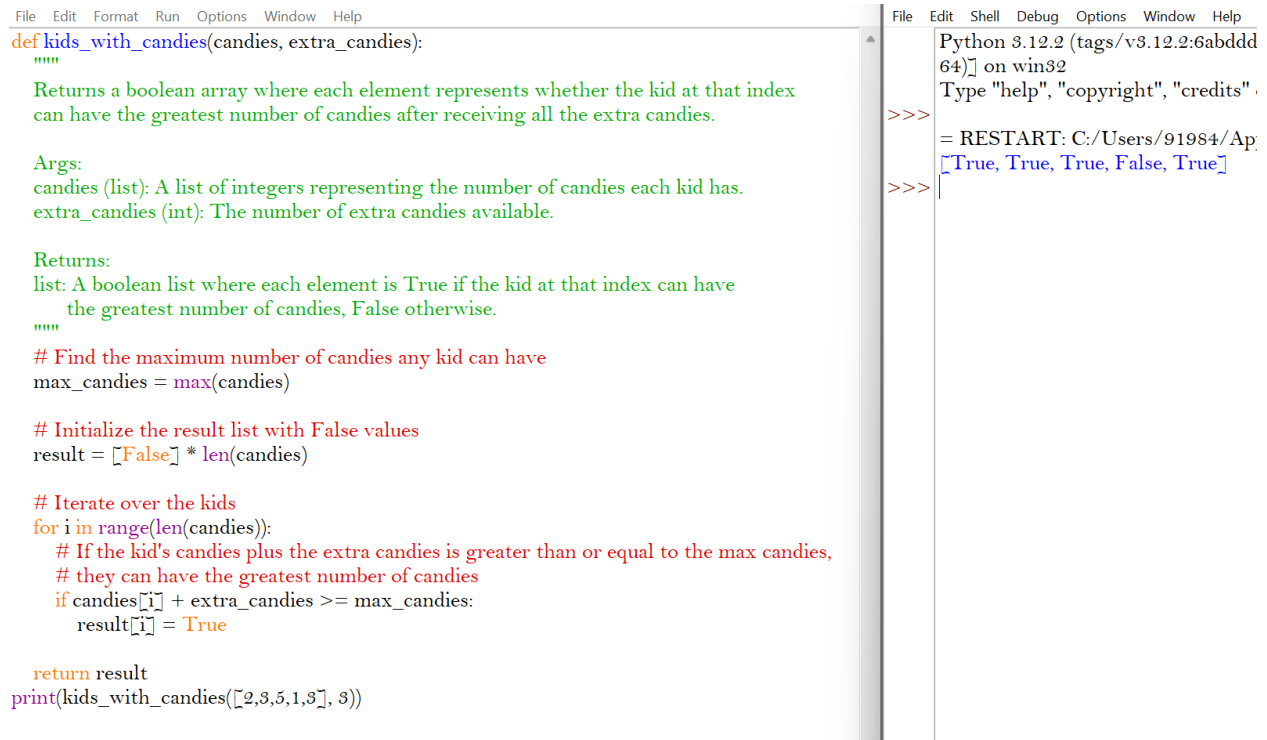

Explanation: The path 0 -> 1 -> 1 is a sequence, but it is not a valid sequence.

Constraints:

● $1 \leq \text{arr.length} \leq 5000$

● $0 \leq \text{arr}[i] \leq 9$

● Each node's value is between [0 - 9].

6. Kids With the Greatest Number of Candies

There are n kids with candies. You are given an integer array `candies`, where each

`candies[i]` represents the number of candies the i th kid has, and an integer `extraCandies`,

denoting the number of extra candies that you have.

Return a boolean array `result` of length n , where `result[i]` is true if, after giving the i th kid

all the `extraCandies`, they will have the greatest number of candies among all the kids, or

false otherwise.

Note that multiple kids can have the greatest number of candies.

Example 1:

Input: candies = [2,3,5,1,3], extraCandies = 3

Output: [true,true,true,false,true]

Explanation: If you give all extraCandies to:

- Kid 1, they will have $2 + 3 = 5$ candies, which is the greatest among the kids.
- Kid 2, they will have $3 + 3 = 6$ candies, which is the greatest among the kids.
- Kid 3, they will have $5 + 3 = 8$ candies, which is the greatest among the kids.
- Kid 4, they will have $1 + 3 = 4$ candies, which is not the greatest among the kids.
- Kid 5, they will have $3 + 3 = 6$ candies, which is the greatest among the kids.

Example 2:

Input: candies = [4,2,1,1,2], extraCandies = 1

Output: [true,false,false,false,false]

Explanation: There is only 1 extra candy.

Kid 1 will always have the greatest number of candies, even if a different kid is given the

extra candy.

Example 3:

Input: candies = [12,1,12], extraCandies = 10

Output: [true,false,true]

Constraints:

- $n == \text{candies.length}$
- $2 \leq n \leq 100$
- $1 \leq \text{candies}[i] \leq 100$
- $1 \leq \text{extraCandies} \leq 50$

```
def maximumGap(num: int) -> int:
    num_str = str(num)
    max_num = num
    min_num = num

    for i in range(10):
        for j in range(10):
            new_str = ''.join([str(j) if c == str(i) else c for c in num_str])
            if new_str[0] == '0' and len(new_str) > 1:
                continue
            new_num = int(new_str)
            if new_num != num:
                max_num = max(max_num, new_num)
                min_num = min(min_num, new_num)

    return max_num - min_num
print(maximumGap(555))
```

>>> 888

7. Max Difference You Can Get From Changing an Integer

You are given an integer num. You will apply the following steps exactly two times:

- Pick a digit x ($0 \leq x \leq 9$).
- Pick another digit y ($0 \leq y \leq 9$). The digit y can be equal to x.

- Replace all the occurrences of x in the decimal representation of num by y .
- The new integer cannot have any leading zeros, also the new integer cannot be 0.

Let a and b be the results of applying the operations to num the first and second times, respectively.

Return the max difference between a and b .

Example 1:

Input: $num = 555$

Output: 888

Explanation: The first time pick $x = 5$ and $y = 9$ and store the new integer in a .

The second time pick $x = 5$ and $y = 1$ and store the new integer in b .

We have now $a = 999$ and $b = 111$ and max difference = 888

Example 2:

Input: $num = 9$

Output: 8

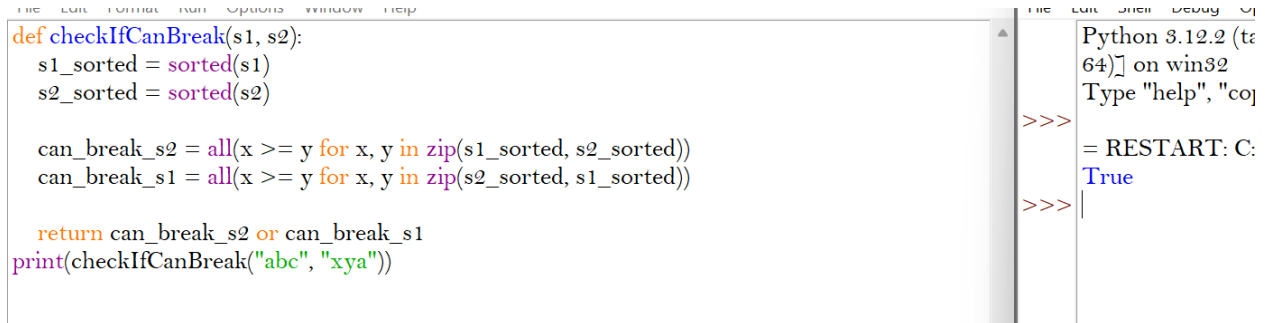

Explanation: The first time pick $x = 9$ and $y = 9$ and store the new integer in a .

The second time pick $x = 9$ and $y = 1$ and store the new integer in b .

We have now $a = 9$ and $b = 1$ and max difference = 8

Constraints:

● $1 \leq \text{num} \leq 108$

```
def checkIfCanBreak(s1, s2):
    s1_sorted = sorted(s1)
    s2_sorted = sorted(s2)

    can_break_s2 = all(x >= y for x, y in zip(s1_sorted, s2_sorted))
    can_break_s1 = all(x >= y for x, y in zip(s2_sorted, s1_sorted))

    return can_break_s2 or can_break_s1
print(checkIfCanBreak("abc", "xya"))
```

Python 3.12.2 (tags/v6.4.0) on win32
Type "help", "copyright", "credits()>>> = RESTART: C:\>>> True

8. Check If a String Can Break Another String

Given two strings: $s1$ and $s2$ with the same size, check if some permutation of string $s1$

can break some permutation of string $s2$ or vice-versa. In other words $s2$ can break $s1$ or

vice-versa.

A string x can break string y (both of size n) if $x[i] \geq y[i]$ (in alphabetical order) for all i

between 0 and $n-1$.

Example 1:

Input: $s1 = "abc"$, $s2 = "xya"$

Output: true

Explanation: "ayx" is a permutation of s2="xya" which can break to string "abc" which is

a permutation of s1="abc".

Example 2:

Input: s1 = "abe", s2 = "acd"

Output: false

Explanation: All permutations for s1="abe" are: "abe", "aeb", "bae", "bea", "eab" and

"eba" and all permutation for s2="acd" are: "acd", "adc", "cad", "cda", "dac" and "dca".

However, there is not any permutation from s1 which can break some permutation from

s2 and vice-versa.

Example 3:

Input: s1 = "leetcode", s2 = "interview"

Output: true

Constraints:

- s1.length == n
- s2.length == n
- $1 \leq n \leq 10^5$
- All strings consist of lowercase English letters.

9. Number of Ways to Wear Different Hats to Each Other

There are n people and 40 types of hats labeled from 1 to 40.

Given a 2D integer array `hats`, where `hats[i]` is a list of all hats preferred by the i th person.

Return the number of ways that the n people wear different hats to each other.

Since the answer may be too large, return it modulo $10^9 + 7$.

Example 1:

Input: `hats = [[3,4],[4,5],[5]]`

Output: 1

Explanation: There is only one way to choose hats given the conditions.

First person choose hat 3, Second person choose hat 4 and last one hat 5.

Example 2:

Input: hats = [[3,5,1],[3,5]]

Output: 4

Explanation: There are 4 ways to choose hats:

(3,5), (5,3), (1,3) and (1,5)

Example 3:

Input: hats = [[1,2,3,4],[1,2,3,4],[1,2,3,4],[1,2,3,4]]

Output: 24

Explanation: Each person can choose hats labeled from 1 to 4.

Number of Permutations of (1,2,3,4) = 24.

Constraints:

- $n == \text{hats.length}$
- $1 \leq n \leq 10$
- $1 \leq \text{hats}[i].\text{length} \leq 40$
- $1 \leq \text{hats}[i][j] \leq 40$
- hats[i] contains a list of unique integers.

10. Next Permutation

A permutation of an array of integers is an arrangement of its members into a sequence or

linear order.

● For example, for arr = [1,2,3], the following are all the permutations of arr: [1,2,3],

[1,3,2], [2, 1, 3], [2, 3, 1], [3,1,2], [3,2,1].

The next permutation of an array of integers is the next lexicographically greater

permutation of its integer. More formally, if all the permutations of the array are sorted in

one container according to their lexicographical order, then the next permutation of that

array is the permutation that follows it in the sorted container. If such arrangement is not

possible, the array must be rearranged as the lowest possible order (i.e., sorted in ascending order).

- For example, the next permutation of $arr = [1,2,3]$ is $[1,3,2]$.
- Similarly, the next permutation of $arr = [2,3,1]$ is $[3,1,2]$.
- While the next permutation of $arr = [3,2,1]$ is $[1,2,3]$ because $[3,2,1]$ does not have a lexicographical larger rearrangement.

Given an array of integers $nums$, find the next permutation of $nums$.

The replacement must be in place and use only constant extra memory.

Example 1:

Input: $nums = [1,2,3]$

Output: $[1,3,2]$

Example 2:

Input: $nums = [3,2,1]$

Output: $[1,2,3]$

Example 3:

Input: $nums = [1,1,5]$

Output: $[1,5,1]$

Constraints:

● $1 \leq \text{nums.length} \leq 100$

● $0 \leq \text{nums}[i] \leq 100$

```
